Abstract—Mininet is an emulator for deploying large networks on the limited resources of a simple single Computer or Virtual Machine. Mininet has been created for enabling research in Software Defined Networking (SDN) and OpenFlow. Mininet emulator allows running unmodified code interactively on virtual hardware on a simple PC. It provides convenience and realism at very low cost. The alternative to Mininet is hardware test beds which are fast, accurate but very expensive and shared. The other option is to use simulator which is very cheap but sometimes slow and require code modification. Mininet offers ease of use, performance accuracy and scalability.

Keywords: Mininet, SDN, OpenFlow

I. INTRODUCTION

There is need to model hosts, switches, links and SDN/OpenFlow controllers. Mininet [1] allows creating topologies of very large scale size up to thousands of nodes and perform test on them very easily. It has very simple command line tools and API. Mininet allows the user to easily create, customize, share and test SDN networks. (Fig. 1).

Fig. 1 Emulating Real Networks in Mininet

Mininet is freely available open source software that emulates OpenFlow devices and SDN controllers. Mininet can simulate SDN networks, can run a controller for experiments [2]. It allows emulating real world network scenarios Couple of SDN controllers are included with in Mininet VM. The default controllers are good but for implementing advance concepts, POX [3] controller is used.

II. SDN AND OPEN FLOW

In traditional networks [4], the data plane and the control plane are tightly coupled on the same device (Fig. 2). Therefore in traditional networks, development of new applications and modification in behavior of existing devices is very difficult task. Software Defined networking (SDN) [5] overcomes these problems by shifting the control logic from devices to the centralized place. The shifted control logic is called SDN Controller or Network Operating System (NOS) [6]. The controller has a global view of the entire network, Therefore by using SDN you can manage the functionality of network in a very efficient manner.

Fig. 2 Separate Control and Data Plane

Open Flow [7] is a standard protocol that is used to provide a communication between controller and dumb device. The controller and dumb devices are called control plane and data plane respectively. The Open Flow controller is responsible for deciding which action is to be performed by the switch. The decision approach is either Reactive or Proactive.

In the Reactive approach, when a packet arrives at a switch, switch does not know how to handle that packet. Therefore switch sends the packet to the controller [8]. Controller is responsible for inserting a flow entry into the flow table of a switch using the openflow protocol. The main disadvantage of this approach is that switch is totally dependent upon controller decision. So when a switch loses the connection with the controller, it cannot handle that packet.

In the Proactive approach [9], the controller pre populates the flow entries in the flow tables of each switch. This approach overcomes the limitation of reactive approach because even if the switch loses the connection with controller, it does not disrupt traffic.

The main advantages of SDN over traditional approach are that it allows you to quickly test and deploy new applications in real network, minimize capital and operating expenses and allows centralized management of each switch.

III. MININET TOPOLOGIES

Mininet contains number of default topologies such as minimal, single, reversed, linear and tree [10]. This section explains these topologies one by one. Understanding naming method for interfaces, hosts and switches is essential for prospering using Mininet. Switches are named from s1 to sN. Hosts are named h1 to hN. Host interfaces are named prefixed with host's name following by Ethernet name starting with 0. First interface of host 'h1' is called 'h1-eth0' and third interface of host 'h2' is called 'h2-eth2'. First port of switch 's1' is named 's1-eth1'. In switches, numbering begins with 1.

A. Minimal

Minimal is very simple topology that contains 1 OpenFlow switch and 2 hosts. It also creates links between switch and two hosts (Fig. 3).

mn--topo minimal

Fig. 3 Minimal Topology

B. Single

It is a simple topology with one openflow switch and k hosts. It also creates a link between switch and k hosts (Fig. 4).

mn--topo single, 4

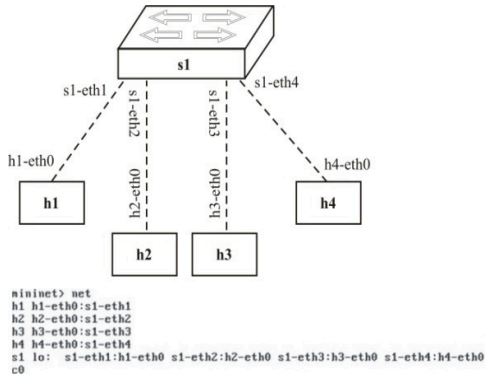

Fig. 4 Single Topology

C. Reversed

It is similar to single topology but connection order is reversed (Fig. 5).

Fig. 5 Reversed Topology

mn--topo reversed, 4

D. Linear

Linear topology contains k switches and k hosts. It also creates a link between each switch and each host and among the switches (Fig. 6).

Fig. 6 Linear Topology

mn--topo linear, 4

E. Tree

Tree topology contains k levels and 2 hosts are attached to per switch (Fig. 7).

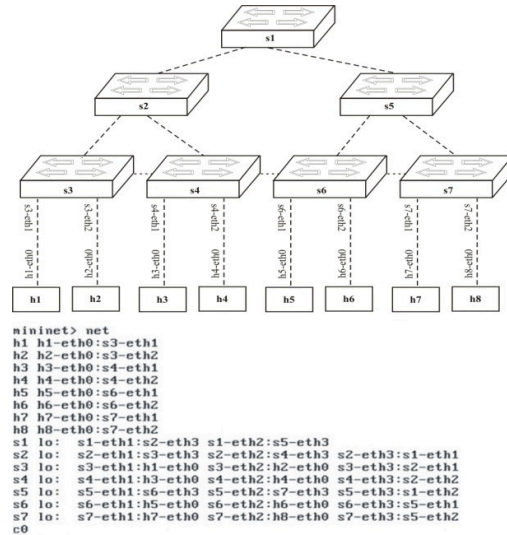

Fig. 7 Tree Topology

mn--topo tree, 3

IV. CREATING CUSTOM TOPOLOGIES

Using Mininet, you can easily create a custom topology [11]. For example creating custom topology having 2 switches and 5 hosts (Fig. 8) needs just writing a few lines of Python [12] code. You can also easily create very complex flexible, robust. You can also configured that topology based on the parameters that are to be pass to it, and reuse that topology for multiple experiments.

Fig. 8 Custom Topology

In the following Listing 1 contain Python code for creating custom topology having 2 switches and 5 hosts. This topology is run in Mininet by using following command.

Python CustomTopologyPerformance.py

```

from mininet.cli import CLI
from mininet.util import dumpNodeConnections
from mininet.node import CPULimitedHost
from mininet.link import TCLink
class SingleTopologyPerformance(Topo):
    def __init__(self, k=3):
        Topo.__init__(self)
        switch=self.addSwitch('s1')
        linkoptions=dict(bw=10, delay='10ms', max_queue_size=1000, use_hf= True)
        for h in range(k):
            host=self.addHost('h'+str(h+1), cpu=.4/k)
            self.addLink(host, switch, **linkoptions)

def performanceTest():
    topo=SingleTopologyPerformance(k=5)
    net=Mininet(topo=topo, host=CPULimitedHost, link=TCLink)
    net.start()
    print 'displaying host connection information'
    dumpNodeConnections(net.hosts)
    print 'Testing network Connectivity'
    net.pingAll()
    print 'Checking bandwidth between host h1 and h3'
    h1,h3 = net.get('h1','h3')
    net.iperf(h1,h3)
    net.stop()
if __name__ == '__main__':
    setLogLevel('info')
    performanceTest()

```

Listing 1 Custom Topology Code

There are number of classes, functions, methods and variables in the Listing 1

1. Topo: It is a base class for Mininet topologies.
2. Add Host (name, cpu = f): It is used for adding a host to the topology which contains two parameters. First parameter specifies the name of host and second specifies the fraction of overall system CPU resources that is to be allocated to the virtual host.
3. Add Switch(): It is used for adding a switch to the topology and returns the switch name, for example s1.
4. Add Link (node1, node2, **link options): It is used for adding a bidirectional link which

contains three parameters. The first, second parameter specify the host and switch name respectively and third parameter specify the dictionary that contain number of options such as bandwidth, delay and loss characteristics, with a maximum queue size.

5. start(): It is used for starting your network.
6. stop(): It is used for stopping your network.
7. Mininet: It is used as a main class to create and manage a network.
8. net. hosts: It is used to show all the hosts in network.
9. ping All (): This is used to check connectivity between all nodes.
10. Set Log Level: There are number of Log Level such as info, debug, and output. Info is recommended as it provides useful information.
11. Dump Node Connections (): Dumps connections to/from a set of nodes.

There are basically two classes available such as CPU Limited Host and TC Link that can be used for performance limiting and isolation.

There are number of ways that these classes may be used, but simple way is to specify them as the default host and link classes to Mininet(), and then to apply the appropriate parameters in the topology.

V. CONTROLLING DEFAULT TOPOLOGY WITH DPCTL

This topology (Fig. 9) creates 1 switch and 3 hosts. The option 'mac' set the mac address of each host according to node number and option 'remote' is to be used to connect switch to remote controller. As shown, hosts can not ping with each other because remote controller is not running, therefore flow table of switch does not contain any flow entry.

```

root@mininet-vm:~# mn --topo single,3 --mac --controller remote
*** Creating network
*** Adding controller
*** Adding hosts:
h1 h2 h3
*** Adding switches:
s1
*** Adding links:
(h1, s1) (h2, s1) (h3, s1)
*** Configuring hosts
h1 h2 h3
*** Starting controller
*** Starting 1 switches
s1
*** Starting CLI:
mininet> pingall
*** Ping: testing ping reachability
h1 -> X X
h2 -> X X
h3 -> X X
*** Results: 100% dropped (0/6 received)

```

Fig. 9 Single Switch, 3 Hosts Topology

There are two methods to add flow entries into flow table of switch, remote controller and 'dpctl' [13] utility that works on port 6634 (Fig. 10). dpctl is a data

path controller that comes with OpenFlow reference distribution and is used to manage the flow table of switch by using 'dpctl' commands. After adding flow entries by using 'dpctl' command, the host h1 and h2 can ping with each other (Fig. 11).

```
root@mininet-vm:~# dpctl dump-flows tcp:127.0.0.1:6634
stats_reply (xid=0x5845adf1): flags=none type=1(flow)
root@mininet-vm:~#
root@mininet-vm:~# dpctl add-flow tcp:127.0.0.1:6634 in_port
=1,actions=output:2
root@mininet-vm:~#
root@mininet-vm:~# dpctl add-flow tcp:127.0.0.1:6634 in_port
=2,actions=output:1
root@mininet-vm:~#
root@mininet-vm:~# dpctl dump-flows tcp:127.0.0.1:6634
stats_reply (xid=0x1bf3b107): flags=none type=1(flow)
cookie=0, duration_sec=24s, duration_nsec=641000000s, tabl
e_id=0, priority=32768, n_packets=0, n_bytes=0, idle_timeout
=60,hard_timeout=0,in_port=1,actions=output:2
cookie=0, duration_sec=7s, duration_nsec=437000000s, table
_id=0, priority=32768, n_packets=0, n_bytes=0, idle_timeout=
60,hard_timeout=0,in_port=2,actions=output:1
```

Fig. 10 Flow Management Using DPCTL

Default idle timeout of each flow entry is 60s. Therefore after 60 seconds, flow entries will expire and needs to be added again and again. So installs a flow entry with longer timeout using following command:

```
# dpctl add-flow tcp:127.0.0.1:6634 in_port = 1,
idle_timeout = 180, actions = output:2
```

```
mininet> h1 ping -c 2 h2
PING 10.0.0.2 (10.0.0.2) 56(84) bytes of data.
64 bytes from 10.0.0.2: icmp_req=1 ttl=64 time=0.503 ms
64 bytes from 10.0.0.2: icmp_req=2 ttl=64 time=0.094 ms

--- 10.0.0.2 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 1002ms
rtt min/avg/max/mdev = 0.094/0.298/0.503/0.205 ms
```

Fig. 11 Connectivity Test

VI. CONCLUSION

Mininet is a platform for rapid network prototyping. It can run unmodified network application code on small networks as well as very large networks. It is an alternative to run SDN experiments on emulated networks. Real systems are very painful to reconfigure. Virtual machines allow easier topology changes but suffer from scalability issues. Simulators are a good alternative but same source code cannot be deployed on real hardware. There are performance issues on

Mininet. The challenges before Mininet are to model networks of very large scale with practical performance.

ACKNOWLEDGMENT

The authors would like to thank Mr. Vipin Gupta from U-Net Solutions, Moga, India for his valuable help.
